Week 3 Live Summary

Functions are a set of statements that perform a task or calculates a value. A function includes a declaration, an optional name, a parameter/argument in parenthesis, and the statement enclosed in braces. Parameters are the names listed in the function's definition while the arguments are the real values passed to the function. Parameters are initialized to the values of the arguments that are supplied.

We started the first 2 pause and practice videos that involved setting up a JSON and JS file and linking the two together. We took API data from the Star Wars API website and pasted it into our JSON file as an array of objects for each character. In the JS file, we created a constant variable "items" and set it to equal "starWarsData.length". Using the stringify method, we sent the "starWarsData" to the console where we were able to see our output of JSON data.
